§ 4. Two-Stage CT Acceleration Experiment on SPICA

SPICA (SPheromak Injector using Conical Accelerator) is a compact toroid (CT) injector developed for LHD [1]. Here, the results of two-stage CT acceleration experiment are described. SPICA consists of a conical acceleration electrode of 2.6 m long (Fig. 1). The inner radius of the outer electrode changes from 0.172 m to 0.075 m to compress the CT. Among the existing CT injectors aiming at fueling, SPICA is the largest machine in the world.

To investigate the performance of SPICA, we have carried out various systematic scan of the pre-fill pressure, the biasing magnetic field strength, \( B_{\text{bias}} \), and the charging voltage of the acceleration bank, \( V_{\text{acc}} \) [2]. The results of \( V_{\text{acc}} \) scan experiment are shown in Fig. 2. The CT velocity, \( v_{\text{CT}} \), is determined from the time-of-flight of the magnetic and/or the density signals measured at different axial location. A remarkable increase in \( v_{\text{CT}} \) with \( V_{\text{acc}} \) is seen in the high \( V_{\text{acc}} \) region of \( V_{\text{acc}} > 7 \) kV (Fig. 2 (a)). This suggests that \( v_{\text{CT}} \) exponentially increases with \( V_{\text{acc}} \). Other than \( v_{\text{CT}} \), the CT magnetic field strength and the CT density also depend on \( V_{\text{acc}} \). As shown in Fig. 2 (b), \( B_{\text{ps}} \) at the port H begins to increase at \( V_{\text{acc}} > 10 \) kV, and finally exceeds \( B_{\text{bias}} \). This indicates the compression effect by the conical acceleration electrode. At the port D, which locates at less than a half of the acceleration electrode (see Fig. 1) and therefore a significant compression effect is not expected, \( B_{\text{pa}} \) tends to saturate at a value similar to \( B_{\text{bias}} \) in the range of \( V_{\text{acc}} < 9 \) kV. As for the density shown in Fig. 2 (c), it increases in the range of \( V_{\text{acc}} < 10 \) kV and then begins to decrease with \( V_{\text{acc}} \). However, the compression effect on the CT density cannot be recognized; i.e. there is no significant difference in \( \bar{n}_e \) measured at various axial location. To achieve the density increase by the compression, the particle confinement time of the CT, \( \tau_p \), should be large enough compared with the CT compression time, \( \tau_{\text{comp}} \), which is not the case here. In other words, it is suggested from the result that \( \tau_p \) is similar or less than \( \tau_{\text{comp}} - 20 \mu s \).
