## **Abstract.**

Energy levels, radiative transition probabilities and autoionization rates for CII including  $1s^2 2l 2l' nl''$  ( $n=2-6$ ,  $l' \leq (n-1)$ ) states were calculated by using multi-configurational Hartree-Fock (Cowan code) method. Autoionizing levels above three thresholds:  $1s^2 2s^2$  ( $^1S$ ),  $1s^2 2s 2p$  ( $^3P$ ),  $1s^2 2s 2p$  ( $^1P$ ) were considered. Branching ratios related to the first threshold and the intensity factor were calculated for satellite lines of CII ion.

The dielectronic recombination rate coefficients to the excited states for  $n=2-6$  are calculated with these atomic data. The rate coefficients are fitted to an analytical formula and the fit parameters are given. The values for higher excited states than  $n=6$  are extrapolated and the total dielectronic recombination rate coefficients are derived. The effective recombination rate coefficient for different electron densities are also derived.

Key words;

autoionizing level, dielectronic recombination, carbon ion, excited states, autoionization rate, radiative transition probabilities, satellite spectra.

## 1. Introduction

In order to solve the rate equation of the populations of ions, it is necessary to include many number of levels of the highly excited states for the case of dense plasma. The population of the excited states are determined mainly by the excitation from the ground state and the recombination from the ions at low densities. When the electron density increases, the excitation processes from the excited states become important. In the case of a recombining plasma, the recombination to each excited state is necessary to estimate the populations of ions. These data are also necessary to obtain the effective recombination rate coefficients at high electron densities.

Dielectronic recombination (DR) is a process which plays an important role in plasma dynamics, and also is a subject of interest in studies of atomic structure. We used the following notations here:  $\gamma$  and  $\gamma'$  are an autoionization state and excited state of an ion  $X_Z$  respectively,  $\alpha = \alpha_n / L S J$  is the stationary state of an ion  $X_{Z+1}$ . The state  $\gamma$  can be produced by dielectronic capture (if photon  $\gamma - \gamma'$  is emitted, then the dielectronic recombination takes place) [1] :

For example, the transitions  $1s2l'nl - 1s^2nl$  are satellite lines to the resonance line  $1s2p-1s^2$ , transitions  $1s2l'nl-1s^22l'' - 1sn'l'nl-1s^2nl$  and of Li-like ions are the satellites to the line  $1snp-1s^2$  of He-like ions. Be-like satellite lines for  $1s2p-1s^2$  lines of He-like ions are connected with the states  $\gamma = 1s2l'2l''nl$ . An intensity factor  $Q_d$  for the transition  $\gamma - \gamma'$  is defined as follows:

$$Q_d(\gamma, \gamma' | \alpha_0) = g_\gamma \frac{A(\gamma, \gamma')}{A_\gamma + \Gamma_\gamma} \Gamma(\gamma, \alpha_0) = g_\gamma A(\gamma, \gamma') K(\gamma, \alpha_0) \quad (2)$$

$$K(\gamma, \alpha_0) = \frac{\Gamma(\gamma, \alpha_0)}{(A_\gamma + \Gamma_\gamma)}, \quad A_\gamma = \sum_{\gamma''} A(\gamma, \gamma''), \quad \Gamma_\gamma = \sum_{\alpha'} \Gamma(\gamma, \alpha') \quad (3)$$

where  $A(\gamma, \gamma)$  is radiative transition probabilities and  $\Gamma(\gamma, \alpha)$  is autoionization rate. Dielectronic satellite spectra of H- and He-like resonance lines ( $1s-np$ ,  $1s^2 - 1snp$ ) have been studied in many papers [2-6].

Recently the dielectronic recombination processes from the ground state of H-like He [7] and He-like C [8] have been studied experimentally. It was measured DR cross section by using a cooled ion beam.

The cross section for DR of  $C^{4+}$  ions had been measured in [8] up to the  $1s2s$  ( $^1,^3S$ ) and  $1s2p$  ( $^1,^3P$ ) excitation thresholds which gives resolved  $1s2s^2\ ^2S$ ,  $1s(2s2p\ ^3P)\ ^2P$ ,  $1s(2s2p\ ^1P)\ ^2P$ ,  $1s2p^2\ ^2D$ ,  $1s2p^2\ ^2S$  levels.

The DR cross section for  $C^+$  ions were studied experimentally [9] and theoretically [10-12]. The studied process was represented as follows [9]:

It was published by Badnell [13] the theoretical calculation of DR total rate coefficients from the ground and metastable levels of C and O ions. The DR rate coefficients to the excited states of CI from CII were calculated recently by Dubau and Kato [14].

Measurements of relative DR cross sections for F-like Xe had been reported by DeWitt [15]. DR onto the ground state of  $Xe^{45+}$  is given schematically as

Recombination rates are obtained when the ion recombines with beam electrons in an ion trap [15].

The more complicated system (Ni-like tantalum) had been theoretically studied by Chen [16]. DR rate coefficients from the ground state  $Ta^{45+}$  had been calculated for the electron temperatures in the range  $0.02 < T < 10$  KeV. This processes can be schematically represented by

The calculation of atomic characteristics was carried out for the intermediate autoionizing states  $3d^{-1} 4n l'$  ( $n < 10$ ),  $3p^{-1} 4n l'$  ( $n < 10$ ) and  $3s^{-1} 4n l'$  ( $n < 7$ ).

In the present paper we consider more simple system - Be-like Carbon ions. We consider three thresholds ( $1s^22s^2$ ,  $1s^22s2p^3P$ ,  $1s^22s2p^1P$ ) where the autoionizing states of  $C^+$  ion are situated. This processes can be schematically represented by

For the threshold ( $1s^22l2l'$ ) we consider the  $1s^22s2p^3P$  and  $1s^22s2p^1P$  as well as the ground state ( $1s^22s^2$ ). We take into account as well as the  $1s^22s^2nl$  excited states the  $1s^22s2p3l$ . Let us note that  $1s^22s2p3l$  states can be autoionized with the intermediate term  $^1P$  ( $1s^22s2p[^1P]3l$ ) and not-autoionized with the intermediate term  $^3P$  ( $1s^22s2p[^3P]3l$ ). This rule works for  $l=s$  and  $l=p$ . The  $1s^22s2p[^3P]3d$  states are in the autoionizing states like the  $1s^22s2p[^1P]3d$  ones. It should be noted that the  $1s^22p^2nl$  states are autoionized for  $n \geq 3$  and they are not autoionized for  $n=2$  ( $1s^22s2p^2$  and  $1s^22p^3$ ). As a result we found the 77 levels up to  $n=6$  (eq.(7)) as the excited levels and the 717 levels as the autoionizing ones ( 230 levels are between the  $1s^22s^2$  and  $1s^22s2p^3P$  thresholds, 140 levels are  $1s^22s2p^3P$  and  $1s^22s2p^1P$  thresholds and 347 levels are above the  $1s^22s2p^1P$  threshold).

## 2. Energy levels, radiative transition probabilities and autoionization rates

We carried out detailed calculations of radiative transition probabilities and auto-ionization rates for the intermediate states  $1s^22s^2(^1S)nl$ ,  $1s^22s2p(^1,3P)nl$  and  $1s^22p^2(^3P, ^1S, ^1D)nl$  ( $n=2 - 6$ ). The atomic energy levels and bound-state wave functions were obtained by using the atomic structure code of Cowan [17]. It was found (see for example Pindzola et al [18]) that using this code, one could obtain good agreement with experimental energies by scaling the electrostatic Slater parameters using the different factor (0.80 in [18]) to correct for correlation effects.

Table Ia lists non-scaled (a) and scaled (b,c) Hartree-Fock energies together with recommended data (d) by Bashkin & Stoner [19] for B-like ion with  $1s^22s^2(^1S)3l$ ,  $1s^22s2p(^1,3P)3l$  and  $1s^22p^2(^3P, ^1S, ^1D)3l$  intermediate states. The scaled factor was equal to 0.85. The difference of the energies of  $1s^22s^2(^1S)nl$ ,  $1s^22s2p(^1,3P)nl$  and

$1s^2 2p^2 (^3P, ^1S, ^1D)nl$  states ( $n=2-3$ ) in the case of calculations with including only the  $n=2-3$  states ("b" column in Table Ia) and in the case of including the  $n=2-6$  states ("c" column in Table Ia) can be explained by the correlation effects. We can see from comparison "a" and "b" energies of Table I that the scaling factor changes energies between  $1000 - 3000\text{cm}^{-1}$ . The superposition configurations ("b" and "c" energies) is shifted the values with  $200 - 1000\text{cm}^{-1}$  only. The difference between these energies ("c") and the recommended energies ("d") are in the range  $400 < E < 7000\text{cm}^{-1}$ . The largest difference takes place for the states with equivalent electrons ( $1s^2 2s 2p^2$ ,  $1s^2 2p^3$ ) and can be explained by the correlation correction. This correction was calculated by perturbation theory (see for example, Ivanova and Safronova [21]) in the frame of two orders by  $1/Z$ - expansion. The second order contribution for the correlation corrections ( $E_2^{corr}$ ) of  $C^+$  for  $1s^2 2s 2p^2 (^4P, ^2D, ^2S, ^2P)$  and  $1s^2 2p^3 (^4S, ^2D, ^2P)$  states is equal to  $7290, -5090, -3200, -11830, 3200, 8620, 10560\text{cm}^{-1}$  correspondingly. The difference between the recommended data [19] ("d") and non-scaled Hartree-Fock data ("a" -  $E^{HF}$ ) is equal to  $4151, -5037, -5171, -8989, 1163, -7812, -13795$  correspondingly. We can see that the largest part of the difference between the recommended data and  $E^{HF}$  can be covered by the  $E_2^{corr}$  values. We have no data of  $E_2^{corr}$  for another states of  $C^+$  ion but we can estimate from this comparison how much we can shift our scaled data calculated in matrixes with superposition of configurations up to  $n=6$  ("c"). We found that the differences between "d" and "c" data for  $1s^2 2s 2p^2 (^4P, ^2D, ^2S, ^2P)$  and  $1s^2 2p^3 (^4S, ^2D, ^2P)$  states are  $922, -1647, 646, 441, -80, -5649, -7152$  correspondingly. Only for two states  $1s^2 2p^3 (^2D, ^2P)$  the scaling and superposition configurations did not solve the problem of the correlation corrections, but the discrepancy was decreased by twice comparing the Hartree-Fock data (column "a" in Table Ia).

Table 1b was prepared almost in the same form as Table 1a but for the  $1s^2 2s^2 (^1S)4l$ ,  $1s^2 2s 2p (^1,3P)4l$  and  $1s^2 2p^2 (^3P, ^1S, ^1D)4l$  intermediate states. The scaled factor 0.85 was used for computing energies of these sates (see column "a" and "b"). The data given in column "a" were computed using complex states  $1s^2 2s^2 (^1S)nl$ ,  $1s^2 2s 2p (^1,3P)nl$  and  $1s^2 2p^2 (^3P, ^1S, ^1D)nl$  with  $n=3,4$  and the states with  $n=3,4,5$  and 6

were took into account for data shown in column “b”. We can see from this table that these data agree well with recommended data from [19]. The difference in energies given in columns “b” and “c” is  $100 - 500\text{cm}^{-1}$ . It is much better than for the energies of  $1s^22s^2(^1S)3l$ ,  $1s^22s2p(^{1,3}P)3l$  and  $1s^22p^2(^3P,^1S,^1D)3l$  intermediate states (see Table Ia). It should be noted that for the more excited states considered in Table 1b (compared to the states in Table Ia) the contribution of correlation effects can be less important and the scaled factor was enough for the correlation part of energy.

Table Ic lists non-scaled (a) and scaled (b,c) Hartree-Fock transition probabilities sum on all the lower levels multiplied on statistical weight of the upper level (weighted radiative transition probabilities -sum(gAr)) together with recommended data (d) by Wiese et al [20] for the same states as in Table Ia. We can see from Table Ib that disagreement of “a, b, c, d” data is not more than 20% except some levels ( $2s^2(^1S)3s\ ^2S$ ,  $2s^2(^1S)3p\ ^2P$ ). Superposition configuration (n=3, 4, 5, 6) only slightly changed Sum(gAr). It should be noted that data in [20] were also obtained by HF method but probably with huge number of configuration.

Tables IIa, b, c, and d list energy levels, weighted radiative transition probabilities and autoionization rates for CII. We computed  $1s^22s^2nl$ ,  $1s^22s2pnl$  and  $1s^22p^2nl$  states with  $n=2-6$  and  $l' \leq (n-1)$  but we included in Table II the data up to  $n=4$  and  $l=s, p, d, f$  since data file was too large. All data are in the order of increasing the energy levels.. Tables IIa includes levels before the first threshold:  $1s^22s^2$  ( $196660\text{ cm}^{-1}$ ). These levels are not autoionizing and we include in this table only radiative transition probabilities. Tables IIb includes levels between the first and the second threshold:  $1s^22s2p\ ^3P$  ( $248975\text{ cm}^{-1}$ ). We included in this table the autoionizing rates also. There is only one decay channel through autoionization for these levels and sum (Aa) is equal to Aa. We can see from Table IIb many zero values for Aa. This means that autoionization rate is very small. We note that all the following levels are included in even ( $1s^22s^2ns$ ,  $1s^22s^2nd$ ,  $1s^22s^2ng$ ,  $1s^22p^2ns$ ,  $1s^22p^2nd$ ,  $1s^22p^2ng$ ,  $1s^22s2pnp$ ,  $1s^22s2pnf$ ,  $1s^22s2pnh$ ) or odd ( $1s^22s^2np$ ,  $1s^22s^2nf$ ,  $1s^22s^2nh$ ,  $1s^22p^2np$ ,  $1s^22p^2nf$ ,  $1s^22p^2nh$ ,  $1s^22s2pns$ ,  $1s^22s2pnd$ ,  $1s^22s2png$  and  $1s^22p^3$ ) complexes. For levels of even complex the non-zero data for autoionizing rate take place for  $^2S$ ,  $^2D$  and  $^2G$  terms:  $1s^22s2pnp\ ^2S \rightarrow 1s^22s^2\epsilon s\ ^2S$ ,  $1s^22s2pnp\ ^2D \rightarrow 1s^22s^2\epsilon d\ ^2D$ ,  $1s^22s2pnf\ ^2G$

→ $1s^2 2s^2 \epsilon g \ ^2G$ . For levels of odd complex the non-zero data for autoionizing rate take place for  $^2P$ ,  $^2F$  and  $^2H$  terms:  $1s^2 2s 2p ns \ ^2P \rightarrow 1s^2 2s^2 \epsilon p \ ^2P$ ,  $1s^2 2s 2p nd \ ^2F \rightarrow 1s^2 2s^2 \epsilon f \ ^2F$ ,  $1s^2 2s 2p ng \ ^2H \rightarrow 1s^2 2s^2 \epsilon h \ ^2H$ . We can see from Table IIb that for all above mentioned levels we obtained non-zero data for  $\Gamma$  when the total angular momentum is conserved. The values of  $A_a$  ( $A_a \equiv \Gamma$ ) for a such direct decay in LS coupling scheme are equal to  $10^{12} - 10^{14} \text{ s}^{-1}$  and  $A_a \gg \text{Sum Ar}$  since  $10^9 \leq \text{Sum Ar} < 10^{11} \text{ s}^{-1}$ . As a result the branching ratio  $K(\gamma, \alpha_0)$  is equal to 1. The non-zero values of  $A_a$  for quartet terms ( $^4L$ ) takes place by relativistic effects.  $A_a$  for the quartet levels is much less than for doublet levels and  $A_a \approx \text{Sum Ar}$ . For these levels ratio  $K(\gamma, \alpha_0) < 1$ .

Tables IIc includes levels between the second  $1s^2 2s 2p \ ^3P$  ( $248975 \text{ cm}^{-1}$ ) and the third threshold:  $1s^2 2s 2p \ ^1P$  ( $299011 \text{ cm}^{-1}$ ). There are 2 decay channels ( $1s^2 2s^2$  and  $1s^2 2s 2p \ ^3P$ ) for the levels of this interval of energy. As we can see from Table IIc the second channel is more preferable than to the first threshold for the levels in this interval of energy. They are levels of types  $1s^2 2s 2p(^1P)nl$  and  $1s^2 2p^2(^3P)nl$ . For decays to the ground state  $1s^2 2s^2$  we can use the same rule of the conservation total angular momentum as above but only for  $1s^2 2s 2p(^1P)nl$  levels. There is no direct decay to the ground state for the autoionizing levels  $1s^2 2p^2(^3P)nl$  ( $1s^2 2p^2(^3P)nl \rightarrow 1s^2 2s^2 \epsilon l$ ). Non-zero value of  $A_a$  of these levels one obtained with the superposition of configurations for the target ( $1s^2 2s^2 \ ^1S + 1s^2 2p^2 \ ^1S$ ). It should be noted that the branching ratios  $K(\gamma, \alpha_0)$  can be determined by the ratios of  $A_a$  for the first channel ( $\alpha_0 = 1s^2 2s^2 \epsilon l$ ) to the sum of  $A_a$  since  $\text{Sum (Ar)} \ll \text{Sum(Aa)}$ .

Tables II d includes levels above the third threshold:  $1s^2 2s 2p \ ^1P$  ( $299011 \text{ cm}^{-1}$ ). There are 3 decay channels:  $1s^2 2s^2$ ,  $1s^2 2s 2p \ ^3P$  and  $1s^2 2s 2p \ ^1P$ . We can see from this table that there are only few levels with non-zero values to the ground state. It can be explained by absence of direct decay of the level situated in this interval of energy ( $1s^2 2p^2(^3P)nl$ ,  $1s^2 2p^2(^1D)nl$ ,  $1s^2 2p^2(^1S)nl$ ) to the ground state ( $1s^2 2s^2$ ). As we said before the branching ratios  $K(\gamma, \alpha_0)$  is really equal to the value of  $A_a(1s^2 2s^2)/\text{Sum(Aa)}$  and as a result  $K(\gamma, \alpha_0) \ll 1$  for the levels in this interval of energy.

### 3. Dielectronic satellite spectra

Autoionizing levels  $1s^22s2pnl$ ,  $1s^22p^2nl$  produce satellite lines to the resonance lines from the  $1s^22s^22p - 1s^22p^22s - 1s^22p^3$  transitions in the region of 900 - 2000 Å. Tables III and IV list wavelengths (WL), weighted radiative transition probabilities ( $gAr$ ), branching ratio (K) and factor of relative intensity (Qd) of dielectronic satellite lines. There are huge number of such lines but we have chosen lines with largest value of  $gAr$  for illustration. We discovered that there are only 53 lines with  $gAr > 10^{10} \text{ s}^{-1}$ . These lines are given in Table IVa (transitions from even complex to odd one) and Table Va (transitions from odd complex to even one). As we showed in Sect.2 (see Table II) the non-zero values of  $Aa$  for levels of odd complex (direct decay from autoionizing levels to  $1s^22s^2$ ) take place for doublet terms with odd L:  $^2P$ ,  $^2F$ ,  $^2H$ . We can see from Table IVa that only for transitions with  $^2F_J$ ,  $^2H_J$  terms for upper level we obtained non-zero values of branching ratios (K) and also Qd. On the contrary Table Va shows that only for transitions with  $^2D_J$ ,  $^2G_J$  terms for upper level can give contribution to dielectronic satellite spectra, since only for these terms we obtained non-zero values of branching ratios (K) and also Qd. It should be noted that this conclusion is applicable for the case of thin plasma where only the lowest level of  $C^{2+}$  ( $1s^22s^2$ ) is populated. The values of  $Aa$  (and so K and Qd) to other states ( $1s^22s2p^{1,3}P$ ) can be different from zero almost for all transitions given in Tables IVa and Va. Table IVb and Vb were organized in similar to Tables IVa and Va but we choose transitions with  $gAr > 10^{9+} \text{ s}^{-1}$ . Also we removed all transitions with zero values of  $Aa$ . As a result there are transitions with  $^2P$ ,  $^2F$ ,  $^2H$  terms of upper states in Table IIIb and transitions with  $^2S$ ,  $^2D$ ,  $^2G$  terms of upper states in Table IVb.

The satellite spectra shown on Tables IVa,b and Va,b covered the interval of wavelength from 406 Å up to 1230 Å. The range of 406 Å up to 950 Å consists of the  $n-2$  transitions with  $n=3-6$ . There are some transitions  $n=6-3$  types ( $2s^2(^1S)6d - 2p^2(^1D)3p$ ) but their contribution to the satellite spectra is very small ( $Qd < 10^7 \text{ s}^{-1}$ ). The largest contribution to satellite spectra ( $\approx 960 \text{ Å}$ ) gives transition with  $\Delta n=0$  ( $2s^2(^1S)nl - 2s2p(^1P)nl$  transitions). We have to note that the contribution of the transitions with  $n \leq 6$  calculated in this section to the total dielectronic satellite lines are only about 1%.

We have to include the contribution from higher levels ( $n \leq 500$ ) in order to obtain the total values. This problem will be considered in the next section.

#### 4. Dielectronic recombination rate coefficients to the excited states

The dielectronic recombination rate coefficients  $\alpha_d(\gamma'|\alpha_0)$ , to the excited state are obtained by summing up the intensity factor  $Q_d(\gamma, \gamma'|\alpha_0)$  (see Eq.(2)) multiplied the exponential factor over the autoionizing levels  $\gamma$  as,

$$\alpha_d(\gamma'|\alpha_0) = 3.3 \times 10^{-24} \left( \frac{I_H}{T_e} \right)^{3/2} \sum_{\gamma} e^{-\frac{E_S}{T_e}} Q_d(\gamma, \gamma'|\alpha_0) / g(\alpha_0) \quad (8)$$

where  $I_H$  is a hydrogen ionization potential (13.606eV) and  $E_S$  is an energy of the autoionizing states counted from the threshold ( $1s^2 2s^2$  in our case) and  $g(\alpha_0)$  is the statistical weight of threshold which equal to 1 in our case.

Sum over  $\gamma$  means sum over all autoionization levels. We calculated  $Q_d(\gamma, \gamma'|\alpha_0)$  values only up to  $n=6$  by Cowan code and summed all the values up to  $n=6$  to obtain  $\alpha_d(\gamma'|\alpha_0)$ . For CII ions,  $2s^2 nl$ ,  $2p^3$ ,  $2s2p3l$  are under the ionization limit. There are two kind of radiative decay in the dielectronic recombination processes, i)  $2p-2s$  transition such as  $2s2pnl - 2s^2 nl$  and ii)  $nl - 2l'$  transition such as  $2p^2 nl - 2p^2 2s$ ,  $2s2pnl - 2s^2 2p$ . For the highly excited states  $2s^2 nl$  ( $n > 6$ ) we consider only the  $2s2pnl - 2s^2 nl$  transition to obtain  $\alpha_d(\gamma'|\alpha_0)$  since only these transitions are dominant for the first case. We used asymptotic formulas for higher level than  $n=6$ . We obtain for these transitions from (8)

$$\alpha_d(2s^2 nl \ ^2 \ell_J | 2s^2 \ ^1S_0) = 3.3 \times 10^{-24} \left( \frac{I_H}{T_e} \right)^{3/2} \times \sum_{S, L, J'} e^{-\frac{E_S}{T_e}} Q_d(2s2p(^{2S+1}P)nl \ ^2L_{J'}, 2s^2 nl \ ^2 \ell_J | 2s^2 \ ^1S_0) \quad (9)$$

For  $2p - 2s$  transitions, we can use our calculated data for  $n=6$  to extrapolate the values for  $n > 6$ :

$$A(2s2p(^{1,3}P)nl \ ^2L_{J'} - 2s^2 nl \ ^2 \ell_J) = A(2s2p(^{1,3}P)6l \ ^2L_{J'} - 2s^2 6l \ ^2 \ell_J) \quad (10)$$

$$\Gamma(2s2p(^{1,3}P)n\ell \ ^2L_{J'}, 2s^2 \ ^1S_0) = \Gamma(2s2p(^{1,3}P)6\ell \ ^2L_{J'}, 2s^2 \ ^1S_0) \left(\frac{6}{n}\right)^3 \quad (11)$$

and the intensity factor  $Q_d$  can be equal to (see eq.(2))

$$Q_d(2s2p(^{1,3}P)n\ell \ ^2L_{J'}, 2s^2 n\ell \ ^2\ell_J | 2s^2 \ ^1S_0) = (2J'+1) \frac{f(n=6)}{1 + (n/6)^3 f'(n=6)} \quad (12)$$

where

$$f(n=6) = A(2s2p(^{1,3}P)6\ell \ ^2L_{J'} - 2s^2 6\ell \ ^2\ell_J) \frac{\Gamma(2s2p(^{1,3}P)6\ell \ ^2L_{J'} | 2s^2 \ ^1S_0)}{\Gamma(2s2p(^{1,3}P)6\ell \ ^2L_{J'})}$$

$$f'(n=6) = \frac{A(2s2p(^{1,3}P)6\ell \ ^2L_{J'})}{\Gamma(2s2p(^{1,3}P)6\ell \ ^2L_{J'})} \quad (13)$$

By using these formulas we can calculate  $Q_d$  for above mentioned transitions with any  $n$ . The values of  $A$  and  $\Gamma$  for these transitions with  $n=6$  are given in Table VIII.

And we obtained instead of eq. (9) for  $n>6$

$$\alpha_d(2s^2 n\ell \ ^2\ell_J | 2s^2 \ ^1S_0) = 3.3 \times 10^{-24} \left(\frac{I_H}{T_e}\right)^{3/2} \sum_{s,L,J'} e^{-\frac{E_s}{T_e}} (2J'+1) \frac{f(n=6)}{1 + \left(\frac{n}{6}\right)^3 f'(n=6)} \quad (14)$$

It should be noted that we take  $E_s$  for the second ( $2s2p \ ^3P$ ) and third ( $2s2p \ ^1P$ ) thresholds are equal to 6.484eV and 12.685 eV respectively. We can see from Table VIII that the values of  $E_s$  are changed from 4.628eV to 4.976eV and from 10.98eV to 11.38eV for  $2s2p(^3P)6l$  and  $2s2p(^1P)6l$  states for different  $l$ . In this case all states with  $n>6$  can be situated in very small interval of energy: 1.856eV - 1.508eV for  $2s2p(^3P)n\ell$  and 1.705eV - 1.305eV for  $2s2p(^1P)n\ell$ . We used  $E_s$  values at  $n=6$  for  $n>6$ .

Results of our calculations of  $\alpha_d(\gamma' | \alpha_0)$  for 36 excited levels are shown on Fig.1a,b,c (even complex) and Fig.2a,b,c (odd complex) as a function of  $T_e$ . Table VI (even) and Table VII (odd) show the atomic data used for  $\alpha_d(\gamma' | 2s^2)$  to the excited states. We can see that the form of curves given by Figs.1 and 2 are very different. The values of  $\alpha_d(\gamma' | 2s^2)$  for  $\gamma'$  related to the even complex ( $2s2p^2$ ,  $2s^2 ns$ ,  $2s^2 nd$ ,  $2s^2 ng$ ,  $2s2p(^3P)3p$ ) are not equal to zero at very low temperature, even  $T_e$  equal to 0.1eV, on the contrary the values of  $\alpha_d(\gamma' | 2s^2)$  for  $\gamma'$  related to the odd complex ( $2s^2 2p$ ,  $2p^3$ ,

$2s^2np$ ,  $2s^2nf$ ,  $2s2p(^3P)3s$ ,  $2s2p(^3P)3d$ ) decrease towards the low temperature. There are curves with two maximums (see Fig.1a) and the first maximum is at very small  $T_e$  around 0.2eV. This maximum can be explained by contribution from the autoionizing levels  $2s2p(^3P)3d$   $^2P_{1/2}$ ,  $^2P_{3/2}$ ,  $^2F_{5/2}$ ,  $^2F_{7/2}$ . These terms are situated very near to the threshold  $1s^22s^2$  ( $196659 \text{ cm}^{-1}$ ) (see Table IIb) and the values of  $Q_d(\gamma, \gamma' | 2s^2)$  for these levels is around  $10^{10} \text{ s}^{-1}$  (see Table VI). By these data we can obtain the maximum value of  $\alpha_d(\gamma' | 2s^2)$  around  $T_e = E_S$  by these four levels ( $2s2p(^3P)3d$   $^2P_{1/2}$ ,  $^2P_{3/2}$ ,  $^2F_{5/2}$ ,  $^2F_{7/2}$ ).

Let us discuss in more detailed  $T_e$  dependence for  $\alpha_d(\gamma' | 2s^2)$  shown on Fig.1a. Table VI lists some  $Q_d(\gamma, \gamma' | 2s^2)$  which were used for calculations of  $\alpha_d(\gamma' | 2s^2)$ . We can see from this table that the largest value of  $Q_d(\gamma, \gamma' | 2s^2)$  for  $\gamma' = 2p^2(^1D)2s[^2D]$  was obtained by transition from the autoionizing  $2s2p(^3P)3d$  [ $^2F_J$ ] levels. The value of  $E_S$  for these levels is 0.13eV. And we can see from Fig.1a that the maximum of  $\alpha_d(\gamma' | 2s^2)$  for  $\gamma' = 2p^2(^1D)2s[^2D]$  is around  $T_e = 0.13 \text{ eV}$ . The values of  $Q_d(\gamma, \gamma' | 2s^2)$  for other  $\gamma$  (see for example  $\gamma = 2s2p(^1P)3d$  [ $^2F_J$ ]) is the same as for  $\gamma = 2s2p(^3P)3d$  [ $^2F_J$ ]) but the values of  $E_S$  for other levels (for example,  $E_S(2s2p(^1P)3d$  [ $^2F_J$ ]) = 6.24eV) are much larger. In the result we the value for the second maximum of  $\alpha_d(\gamma' | 2s^2)$  is smaller than for the first one. This is exactly what we found for the levels with  $\gamma' = 2s^23d$ ,  $2s^24s$  and  $2s^24d$  (see Table VI and Fig.1a). We can see two maximums for these levels around  $T_e = 0.13 \text{ eV}$  and  $T_e = 6.24 \text{ eV}$ . The ratio of values of the first to the second maximums of  $\alpha_d(2s^2nl | 2s^2)$  decreases with increasing of  $n$ . We see from Figs.1a and 1c that this ratio is almost equal 1 and 0.1 for  $\alpha_d(2s^23d | 2s^2)$  and  $\alpha_d(2s^25d | 2s^2)$  respectively. This conclusion can be confirmed by data of  $Q_d(\gamma, \gamma' | 2s^2)$  given in Table VI (see  $Q_d(\gamma, \gamma' | 2s^2)$  for  $\gamma' = 2s^2nd$ ). It should be noted that the first maximum is disappeared for the  $\alpha_d(2s^2nl | 2s^2)$  with high  $l$  (see  $\alpha_d(2s^2ngl | 2s^2)$  given in Fig.1c) because no transitions from  $2s2p(^3P)3d$  [ $^2F_J$ ] levels. We can see from Table VI that there are no direct transitions of these type ( $2s^2ng - 2s2p(^3P)3d$ ).

Fig.1b demonstrates  $\alpha_d(\gamma' | 2s^2)$  for  $\gamma' = 2s2p(^3P)3p$ . These levels are situated very near under the first threshold  $2s^2$  and the  $2s2p(^3P)3p - 2s2p(^3P)3d$  transition probabilities can be small since the energy differences are very small. We can see

from Table VI that  $Q_d(\gamma, \gamma' | 2s^2) < 10^9 s^{-1}$  for  $\gamma' = 2s2p(^3P)3p$ . In this case the value of  $\alpha_d(2s2p(^3P)3p | 2s^2)$  can be smaller than the value of  $\alpha_d(2s2p^2 | 2s^2)$ . Our conclusion agrees with  $\alpha_d(\gamma' | 2s^2)$  shown by Fig.1b.

We can use asymptotic formula given in paper [22] in order to obtain  $E_S$  for  $2s2p(^3P)n\ell$  and  $2s2p(^1P)n\ell$  states as function of  $n\ell$  as follows. We obtain the energy counted from the threshold:

$$E(1s^2 2s2pn\ell) - E(1s^2 2s2p) = -\frac{Z^2}{2n^2} + 2ZE_1(1s, n\ell) + ZE_1(2s, n\ell) + ZE_1(2p, n\ell) \quad (15)$$

where  $Z$  is the nuclear charge and  $E_1(1s, n\ell)$ ,  $E_1(2s, n\ell)$ ,  $E_1(2p, n\ell)$  are the first order correction which can be represented for the large  $n$  in the form:

$$E_1(1s, n\ell) = \frac{1}{n^2} - \frac{a(1s, \ell)}{n^3}, \quad E_1(2s, n\ell) = \frac{1}{n^2} - \frac{a(2s, \ell)}{n^3}, \quad E_1(2p, n\ell) = \frac{1}{n^2} - \frac{a(2p, \ell)}{n^3} \quad (16)$$

where numerical data for  $a(1s, \ell)$ ,  $a(2s, \ell)$ ,  $a(2p, \ell)$  are given in [22]. Finally we can rewrite eq.(15) by using method of screening constant:

$$E(1s^2 2s2pn\ell) - E(1s^2 2s2p) = -\frac{1}{2n^2} \left( Z - 4 + \frac{1}{n} b(\ell) \right)^2 \quad (17)$$

where for  $b(\ell) = 2a(1s, \ell) + a(2s, \ell) + a(2p, \ell)$ . In the case of  $\ell = s$  we obtain from [22]  $b(s) = 2.211$ . In the result for our ion ( $Z=6$ ) we can find for s-state:

$$E(1s^2 2s2pns) - E(1s^2 2s2p) = -\frac{1}{2n^2} \left( 2 + \frac{2.211}{n} \right)^2 \quad (18)$$

that gives for  $n=6$ ,  $-0.07791 \text{ a.u.} = -2.120 \text{ eV}$ . We obtain for  $E_S = (6.484 - 2.120) = 4.364 \text{ eV}$  and  $E_S = (12.685 - 2.120) = 10.565 \text{ eV}$  which agree very well with data given in Table VIII (the four first lines) obtained by Cowan code. Therefore we can use eq.(16) for estimation of  $E_S$  as function of  $n$ . We simplify eq.(16) for high  $Z$  and use only the first term:

$$E_S(2s2p(^3P)n\ell) = 6.484 - \frac{54.42}{n^2}, \quad E_S(2s2p(^1P)n\ell) = 12.685 - \frac{54.42}{n^2} \quad (19)$$

## 5. Total dielectronic recombination rate coefficients

The total dielectronic recombination rate coefficient is obtained by the sum of all the levels,

$$\alpha_d^l = \sum_{n=2}^{\infty} \alpha_d \left( 2s^2 n \ell^2 \ell_J \middle| 2s^2 \ ^1S_0 \right) + \sum_{\text{LSJ}} \left[ \alpha_d \left( 2s2p^2(\text{LSJ}) \middle| 2s^2 \ ^1S_0 \right) + \alpha_d \left( 2p^3(\text{LSJ}) \middle| 2s^2 \ ^1S_0 \right) + \sum_{\ell} \alpha_d \left( 2s2p[{}^3P]3\ell(\text{LSJ}) \middle| 2s^2 \ ^1S_0 \right) \right] \quad (20)$$

The summation in eq.(20) is done up to  $n = 500$  to obtain the total dielectronic recombination rate coefficient. In Fig.3,  $\alpha_d(2s^2 n \ell / 2s^2)$  is plotted against the principal quantum number  $n$ . We can see that the distribution is different for the different  $l$ . The contribution of high  $l$  is large for smaller  $n$  although that is small for larger  $n$ .

Fig.3 demonstrates  $n$ -dependencies of dielectronic recombination rate coefficient ( $\alpha_d(2s^2 n \ell / 2s^2)$ ) calculated by using eqs.(13, 14) for  $T_e = 6\text{eV}$ . It should be noted that we sum on  $J$  in (14). We can see from Fig.3 that the values  $\alpha_d(2s^2 n \ell / 2s^2)$  are almost constant for  $n=7 - 50$ . It can be explained that the contribution of the term  $f(n=6)(n^3/6^3)$  is very small in this interval of  $n$ ; which means  $\Gamma$  is much larger than  $Ar$ . For example, the value of  $f(n=6)$  for  $6s$  state with  $J'=0.5$  equal to  $0.385 \times 10^{-3}$  (see the third line in Table VIII:  $0.196 \times 10^{+10} / 0.509 \times 10^{+13}$ ). We obtain for this term 3.56 for  $n=100$  and the result  $\alpha_d(2s^2 100s \ell / 2s^2) / \alpha_d(2s^2 6s \ell / 2s^2) = 0.358$ . The 1% contribution is obtained for  $n=381$ .

Fig.4 gives the sum of  $\alpha_d(2s^2 n \ell / 2s^2)$  over  $n$  from  $n=7$  to  $n=N_0$  for the same value of  $T_e$  as in Fig.3 ( $T_e = 6\text{eV}$ ). We can see that  $\alpha_d^N(2s^2 \ell / 2s^2)$

$$\alpha_d^N(2s^2 \ell / 2s^2) = \sum_{n=7}^N \alpha_d(2s^2 n \ell / 2s^2) \quad (21)$$

reaches constant for  $n \geq 300$ . Sum of  $\alpha_d^N(2s^2 \ell / 2s^2)$  over  $l=s, p, d, f, g$  is less stable (see Fig.4) and 1% error as found for  $N=500$  comparing to the total for  $N=1000$ . Fig.5 gives these data with  $N=500$  as function of  $T_e$ . It should be noted that we have one maximum for  $\alpha_d^N(2s^2 \ell / 2s^2)$  around 10 - 12 eV which is near the threshold  $2s2p \ ^1P$ .

There is no apparent maximum near the  $2s2p(^3P)$  threshold since radiative transition probabilities  $A(2s2p(^3P)n\ell - 2s^2n\ell)$  (and  $Q_d$  in this case) is much smaller than that with singlet intermediate momentum. The maximum around  $Te=0.2eV$  for  $\alpha_d$  are mainly due to the contribution of states with  $2s2p3d$  (see Figs.1 and 2). Their contribution to the states with  $n=2 - 6$  is shown in Fig.5 also together with sum over all state. This resulting contribution (solid line on Fig.5) gives total dielectronic recombination rate coefficient for CII ion.

The calculated total dielectronic recombination rate coefficient by Badnell (1988 [23], 1987) [24] and Nussbaumer and Storey (1983) [25], (1984) [26], are shown in Fig. 5 for comparison. The data by Badnell are larger by factor two than ours around  $Te = 10 eV$  and smaller more than factor of two at low  $Te$ . The difference at high  $Te$  ( $\approx 10eV$ ) should be explained by different method for calculation the sum over  $n$  for  $\alpha_d$  (see eq. (9)). In Refs.23, 24 the sum over  $n$  was converted to an integral which was evaluated up to  $n=500$  using Simpson's rule. Also it was used in these papers the Coulomb-Bethe approximation for calculations autoionization rates (see eq. (3.3) in [24]) which can caused the difference in calculation  $Q_d$  for high  $n$  (see eqs.(12), (13)). There are no atomic data in papers [23-26] in order to explain exactly the difference in results except data for total and effective dielectronic recombination rate coefficients. Table IX lists comparison for some transitions. We can see that the difference in results is not more than 15 -30%. This difference can be explained by using different transition energies for calculations of radiative transition probabilities since  $Q_d \approx Ar$  when  $Aa \gg Ar$ . We used data obtained by Cowan code. Small values of transition energy it can make difference in 2-15 % between Cowan data and more accurate data given in Refs.19, 20 and used in papers [23-26]. For example the wavelength for  $2s2s2p[^3P]3p(^2D)-2s2p[^3P]3d(^2F)$  transitions is equal to 8797.3A (see Table IIa in [26]) and 10090.1 ( $^2D_{3/2}-^2F_{5/2}$ ), 10092.8 ( $^2D_{5/2}-^2F_{7/2}$ ), 10136.9 ( $^2D_{5/2}-^2F_{5/2}$ ) by our calculations. In the result we can explain the large disagreement for  $\alpha_d$  for this line shown in Table IX. Certainly we can recalculate the value of  $\alpha_d$  for this line but there are only a little energy data certainly known by experiment for CII and we decided to use theoretical data for all set of our data. In the result we could not explain the

difference in total  $\alpha_d$  for low  $T_e \approx 0.3$  eV (see Fig.5) since we do not know exactly which set of energy was used in [23-26] for calculations of radiative transition probabilities. Also the values of  $\alpha_d$  can be changed very much by the  $E_s$  value (see eq.(8)) which is very sensitive for the levels near threshold.

## 6. The parametrization of the dielectronic recombination rate coefficients

It is convenient to give the rate coefficients in analytical formulae for the use in the various application codes. We have fitted the rate coefficients in the following formula,

$$\alpha_d(\gamma | \alpha_0) = \sum_i A_i e^{-\frac{E_i}{T_e}} T_e^{-3/2} \quad \text{in cm}^3 \text{s}^{-1} \quad (22)$$

where  $E_i$  and  $T_e$  are in eV. The four fitting parameters for each excited states are listed in Table X. It should be noted that a little bit different formula with five fitting parameters was used by Nussbaumer and Storey (1983) [25]

## 7. Effective recombination rate coefficient of Carbon atom

In plasmas, there are three kinds of recombination processes; the radiative, dielectronic and three body recombination. For the recombination of C III to C II, the dielectronic recombination is the most dominant process for  $T_e > 1$  eV at low densities. We constructed a collisional radiative model for carbon atom and ions including the levels up to  $n = 4$  and derived the effective emission and ionization rate coefficients for an ionizing plasma. In this paper we have derived the effective recombination rate coefficients using the dielectronic recombination rate coefficients to the excited states obtained in the previous sections. We have calculated the effective recombination by the following formula,

$$\alpha_{\text{eff}} = \sum_i [A_{i1} + C_{i1}] n(i) + \alpha_t(1) n_e + \alpha_r(1) + \alpha_d(1) \quad (23)$$

where  $A_{i1}$  and  $C_{i1}$  are the radiative transition probability and the de-excitation rate coefficients from  $i$  to 1 level,  $n(i)$  the population density of  $i$  level,  $\alpha_t(1)$ ,  $\alpha_r(1)$ , and

$\alpha_d(1)$  are the three body, radiative and dielectronic recombination to the ground state 1, respectively. The contribution to the states higher than  $n = 4$  is estimated by assuming the threshold by thermal limit.

The effective recombination rate coefficients depend on the electron density very much since the electron is captured to the high  $n$  levels through dielectronic recombination. In Fig. 6, the effective recombination rate coefficients including the radiative, three body and dielectronic recombination are plotted as a function of electron temperature for the several electron densities. The decrease of the rate coefficient at medium densities is due to the decrease of the dielectronic recombination and the increase of the rate coefficients at high density of  $10^{18} \text{ cm}^{-3}$  is due to the three body recombination.

The dielectronic recombination process is also sensitive to the electric field. An electric field increases the rate coefficients due to the Stark mixing at high  $n$  levels but on the other hand decreases due to the field ionization. Then we have to take into account this effect as well as the density effect in plasmas. This microfield effect is most dominant around  $n_e = 10^8 \text{ cm}^{-3}$  (Reisenfeld (1992) [27]) and the collisional effect is more significant than the microfield for  $n_e > 10^{10} \text{ cm}^{-3}$ .

## 8. Conclusion

Wavelengths, weighted radiative transitions probabilities and branching ratios together with factor intensities were calculated in order to build the dielectronic satellite spectra and to obtain dielectronic rates coefficients into the excited states. From comparison with available theoretical and experimental data we can be sure that accuracy of our data for energies is 0.1 - 1%. This is very important since we should be very accurate for dividing level on non-autoionizing and autoionizing for sum over all state for calculations of dielectronic rate coefficients. The accuracy of data for radiative and non-radiative transition probabilities is much worse than the energy, especially for last one since these data depended on the energy of free electrons.

We have to note that the contribution from the  $2s2p3d$  state gives the first maximum around the first threshold ( $2s^2 \ ^1S$ ) and  $2p-2s$  transition with  $n=4-500$  creates

the second maximum between the second ( $2s2p\ ^3P$ ) and third ( $2s2p\ ^1P$ ) threshold. In the result the dielectronic recombination rate coefficient has two maximum in large interval of  $T_e$ . By a such behavior the transitions with  $n \leq 6$  give only 1% to the total dielectronic recombination rate coefficient at  $T_e = 10\text{eV}$  and including the contribution from higher levels ( $n \leq 500$ ) provides another 99% that confirm conclusion that it is very important to take into account these transitions.

## Publication List of NIFS-DATA Series

- NIFS-DATA-1 Y. Yamamura, T. Takiguchi and H. Tawara,  
*Data Compilation of Angular Distributions of Sputtered Atoms*;  
Jan. 1990
- NIFS-DATA-2 T. Kato, J. Lang and K. E. Berrington,  
*Intensity Ratios of Emission Lines from OV Ions for Temperature  
and Density Diagnostics* ; Mar. 1990 [ *At Data and Nucl Data Tables*  
44(1990)133]
- NIFS-DATA-3 T. Kaneko,  
*Partial Electronic Straggling Cross Sections of Atoms for Protons*  
;Mar. 1990
- NIFS-DATA-4 T. Fujimoto, K. Sawada and K. Takahata,  
*Cross Section for Production of Excited Hydrogen Atoms  
Following Dissociative Excitation of Molecular Hydrogen by  
Electron Impact* ; Mar. 1990
- NIFS-DATA-5 H. Tawara,  
*Some Electron Detachment Data for  $H^-$  Ions in Collisions with  
Electrons, Ions, Atoms and Molecules –an Alternative Approach to  
High Energy Neutral Beam Production for Plasma Heating–*;  
Apr. 1990
- NIFS-DATA-6 H. Tawara, Y. Itikawa, H. Nishimura, H. Tanaka and Y. Nakamura,  
*Collision Data Involving Hydro-Carbon Molecules* ; July 1990  
[Supplement to *Nucl. Fusion* 2(1992)25]
- NIFS-DATA-7 H.Tawara,  
*Bibliography on Electron Transfer Processes in Ion-  
Ion/Atom/Molecule Collisions –Updated 1990–*; Aug. 1990
- NIFS-DATA-8 U.I.Safronova, T.Kato, K.Masai, L.A.Vainshtein and A.S.Shlyapzeva,  
*Excitation Collision Strengths, Cross Sections and Rate  
Coefficients for OV, SiXI, FeXXIII, MoXXXIX by Electron Impact  
( $1s^22s^2-1s^22s2p-1s^22p^2$  Transitions)* Dec.1990
- NIFS-DATA-9 T.Kaneko,  
*Partial and Total Electronic Stopping Cross Sections of Atoms and  
Solids for Protons*; Dec. 1990
- NIFS-DATA-10 K.Shima, N.Kuno, M.Yamanouchi and H.Tawara,  
*Equilibrium Charge Fraction of Ions of  $Z=4-92$  (0.02-6 MeV/u) and  
 $Z=4-20$  (Up to 40 MeV/u) Emerging from a Carbon Foil*; Jan.1991  
[*AT.Data and Nucl. Data Tables* 51(1992)173]

- NIFS-DATA-11 T. Kaneko, T. Nishihara, T. Taguchi, K. Nakagawa, M. Murakami, M. Hosono, S. Matsushita, K. Hayase, M. Moriya, Y. Matsukuma, K. Miura and Hiro Tawara,  
*Partial and Total Electronic Stopping Cross Sections of Atoms for a Singly Charged Helium Ion: Part I*; Mar. 1991
- NIFS-DATA-12 Hiro Tawara,  
*Total and Partial Cross Sections of Electron Transfer Processes for  $Be^{q+}$  and  $B^{q+}$  Ions in Collisions with H,  $H_2$  and He Gas Targets - Status in 1991-*; June 1991
- NIFS-DATA-13 T. Kaneko, M. Nishikori, N. Yamato, T. Fukushima, T. Fujikawa, S. Fujita, K. Miki, Y. Mitsunobu, K. Yasuhara, H. Yoshida and Hiro Tawara,  
*Partial and Total Electronic Stopping Cross Sections of Atoms for a Singly Charged Helium Ion : Part II*; Aug. 1991
- NIFS-DATA-14 T. Kato, K. Masai and M. Arnaud,  
*Comparison of Ionization Rate Coefficients of Ions from Hydrogen through Nickel* ; Sep. 1991
- NIFS-DATA-15 T. Kato, Y. Itikawa and K. Sakimoto,  
*Compilation of Excitation Cross Sections for He Atoms by Electron Impact*; Mar. 1992
- NIFS-DATA-16 T. Fujimoto, F. Koike, K. Sakimoto, R. Okasaka, K. Kawasaki, K. Takiyama, T. Oda and T. Kato,  
*Atomic Processes Relevant to Polarization Plasma Spectroscopy* ; Apr. 1992
- NIFS-DATA-17 H. Tawara,  
*Electron Stripping Cross Sections for Light Impurity Ions in Colliding with Atomic Hydrogens Relevant to Fusion Research*; Apr. 1992
- NIFS-DATA-18 T. Kato,  
*Electron Impact Excitation Cross Sections and Effective Collision Strengths of N Atom and N-Like Ions -A Review of Available Data and Recommendations-* ; Sep. 1992
- NIFS-DATA-19 Hiro Tawara,  
*Atomic and Molecular Data for  $H_2O$ , CO &  $CO_2$  Relevant to Edge Plasma Impurities*, Oct. 1992
- NIFS-DATA-20 Hiro. Tawara,  
*Bibliography on Electron Transfer Processes in Ion-Ion/Atom/Molecule Collisions -Updated 1993-*; Apr. 1993

- NIFS-DATA-21 J. Dubau and T. Kato,  
*Dielectronic Recombination Rate Coefficients to the Excited States of C I from C II*; Aug. 1994
- NIFS-DATA-22 T. Kawamura, T. Ono, Y. Yamamura,  
*Simulation Calculations of Physical Sputtering and Reflection Coefficient of Plasma-Irradiated Carbon Surface*; Aug. 1994
- NIFS-DATA-23 Y. Yamamura and H. Tawara,  
*Energy Dependence of Ion-Induced Sputtering Yields from Monoatomic Solids at Normal Incidence*; Mar. 1995
- NIFS-DATA-24 T. Kato, U. Safronova, A. Shlyaptseva, M. Cornille, J. Dubau,  
*Comparison of the Satellite Lines of H-like and He-like Spectra*; Apr. 1995
- NIFS-DATA-25 H. Tawara,  
*Roles of Atomic and Molecular Processes in Fusion Plasma Researches - from the cradle (plasma production) to the grave (after-burning) -*; May 1995
- NIFS-DATA-26 N. Toshima and H. Tawara  
*Excitation, Ionization, and Electron Capture Cross Sections of Atomic Hydrogen in Collisions with Multiply Charged Ions*; July 1995
- NIFS-DATA-27 V.P. Shevelko, H. Tawara and E. Salzborn,  
*Multiple-Ionization Cross Sections of Atoms and Positive Ions by Electron Impact*; July 1995
- NIFS-DATA-28 V.P. Shevelko and H. Tawara,  
*Cross Sections for Electron-Impact Induced Transitions Between Excited States in He:  $n, n'=2,3$  and 4*; Aug. 1995
- NIFS-DATA-29 U.I. Safronova, M.S. Safronova and T. Kato,  
*Cross Sections and Rate Coefficients for Excitation of  $\Delta n = 1$  Transitions in Li-like Ions with  $6 < Z < 42$* ; Sep. 1995
- NIFS-DATA-30 T. Nishikawa, T. Kawachi, K. Nishihara and T. Fujimoto,  
*Recommended Atomic Data for Collisional-Radiative Model of Li-like Ions and Gain Calculation for Li-like Al Ions in the Recombining Plasma*; Sep. 1995
- NIFS-DATA-31 Y. Yamamura, K. Sakaoka and H. Tawara,  
*Computer Simulation and Data Compilation of Sputtering Yield by Hydrogen Isotopes ( $1H^+$ ,  $2D^+$ ,  $3T^+$ ) and Helium ( $4He^+$ ) Ion Impact from Monoatomic Solids at Normal Incidence*; Oct. 1995

NIFS-DATA-32

T. Kato, U. Safronova and M. Ohira,  
*Dielectronic Recombination Rate Coefficients to the Excited  
States of CII from CIII; Feb. 1996*
