

§5. Measurement Method of Thoron Exhalation Rate from Wall

Okamoto, K., Iida, T. (Dept. Nucl. Sch. Eng., Nagoya Univ.)  
Obayashi, H., Yamanishi, H.

We have studied a new type of passive monitors with solid state nuclear track detector (SSNTD). Figure 1 shows the passive integrating  $^{222}\text{Rn}$  and  $^{220}\text{Rn}$  cup monitors. To control  $^{222}\text{Rn}$  or  $^{220}\text{Rn}$  exchange rate, we have made a 5 mm filtered opening for  $^{222}\text{Rn}$  monitor and four openings of diameter 20 mm for  $^{220}\text{Rn}$  monitor.

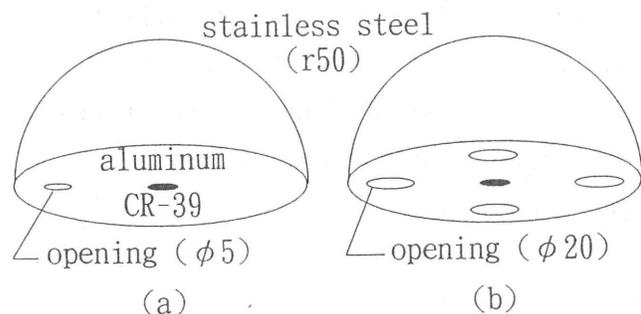

Fig. 1 Passive integrating (a)  $^{222}\text{Rn}$  and (b)  $^{220}\text{Rn}$  cup monitors.

Calibrations of the  $^{222}\text{Rn}$  monitors were performed in high  $^{222}\text{Rn}$  concentration air. The calibration factor was derived to be  $(4.17 \pm 0.24) \times 10^{-3} \text{ tracks} \cdot \text{cm}^{-2} (\text{Bq} \cdot \text{m}^{-3} \cdot \text{h})^{-1}$ . Calibration experiment of the  $^{220}\text{Rn}$  monitors is quite difficult because of the short half-life of  $^{220}\text{Rn}$  (55.6 s). Therefore, the calibration factors of both monitors have been calculated by using molecular diffusion model. The calculated factors were  $4.71 \times 10^{-3}$  and  $0.62 \times 10^{-3} \text{ tracks} \cdot \text{cm}^{-2} (\text{Bq} \cdot \text{m}^{-3} \cdot \text{h})^{-1}$  for  $^{222}\text{Rn}$  and  $^{220}\text{Rn}$  monitors, respectively.

The  $^{220}\text{Rn}$  concentrations have been measured with six pairs of cup monitors in the various dwellings. The results in a dwelling with soil wall are shown in Fig. 2. The  $^{220}\text{Rn}$  concentration at a distance of  $X$  m from wall could be expressed by following equation<sup>1)</sup>

$$Q(X) = \frac{E_{\text{Tn}}}{\sqrt{\lambda_{\text{Tn}} \cdot D}} \exp(-\sqrt{\lambda_{\text{Tn}}/D} X), \quad (1)$$

where  $Q(X)$  is the  $^{220}\text{Rn}$  concentration at a distance of  $X$  m from wall in  $\text{Bq} \cdot \text{m}^{-3}$ ,  $E_{\text{Tn}}$  is the  $^{220}\text{Rn}$  exhalation rate from wall in  $\text{Bq} \cdot \text{m}^{-2} \cdot \text{s}^{-1}$ ,  $\lambda_{\text{Tn}}$  is the  $^{220}\text{Rn}$  decay rate in  $\text{h}^{-1}$ ,  $D$  is the effective diffusion coefficient of  $^{220}\text{Rn}$  in air in  $\text{m}^2 \cdot \text{s}^{-1}$ , and  $X$  is the distance from wall in m.

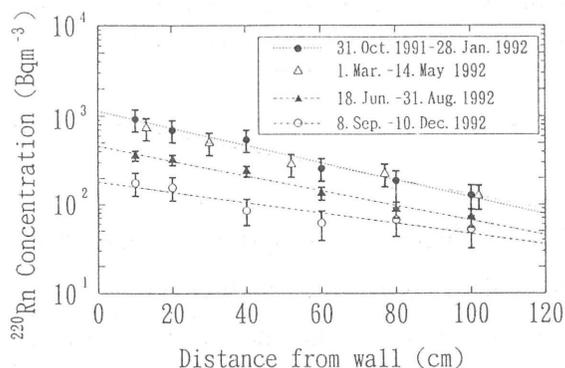

Fig. 2 The distributions of  $^{220}\text{Rn}$  concentrations indoors.

The values of  $E_{\text{Tn}}$  and  $D$  have been determined by using the least squares method. The calculated values of  $E_{\text{Tn}}$  ranged from 0.8 to  $6.4 \text{ m}^2 \cdot \text{s}^{-1}$  in the dwellings with soil wall. The exhalation rates from soil walls show more than ten times as much as those from brick and heavy concrete ranging from 0.01 to  $0.11 \text{ Bq} \cdot \text{m}^{-2} \cdot \text{s}^{-1}$ . The annual mean effective dose equivalent due to  $^{220}\text{Rn}$  progeny was expected to be  $0.67 \text{ mSv} \cdot \text{y}^{-1}$  in the dwellings with soil wall<sup>2)</sup>.

Since the half-life of  $^{222}\text{Rn}$  is 3.8235 d, we could not use the same procedure for measuring the  $^{222}\text{Rn}$  exhalation rate from wall. Then, we thought a new equipment that consists of three boxes between which filters are positioned to make the difference of  $^{222}\text{Rn}$  concentrations. When we set the equipment on the wall, we could obtain the  $^{222}\text{Rn}$  exhalation rate from the differences.
